Enzyme activity = moles of substrate converted per unit time = rate \times reaction volume. Enzyme activity is a measure of the quantity of active enzyme present and is thus dependent on conditions, which should be specified. The SI unit is the katal, 1 katal = 1 mol s⁻¹, but this is an excessively large unit.

Enzymes: Function, definition, and examples

Protein - Protein - Inhibition of enzymes: Some molecules very similar to the substrate for an enzyme may be bound to the active site but be unable to react. Such molecules cover the active site and thus prevent the binding of the actual substrate to the site. This inhibition of enzyme action is of a competitive nature, because the inhibitor molecule actually competes with the substrate for ...

Enzymes have multiple regions that can be activated by co-factors to turn them on and off. The co-factors are usually vitamins consumed through various food sources and open up the active site on the enzyme. Active sites are where reactions take place on an enzyme and can only act upon one substrate, which can be other proteins or sugars.

Digestive enzymes such as pepsin and chymotrypsin, for example, are able to act on almost any protein, as they must if they are to act upon the varied types of proteins consumed as food. On the other hand, thrombin, which reacts only with the protein fibrinogen, is part of a very delicate blood-clotting mechanism and thus must act only on one compound in order to maintain the proper functioning of the system.

Protein - Protein - The mechanism of enzymatic action: An enzyme attracts substrates to its active site, catalyzes the chemical reaction by which products are formed, and then allows the products to dissociate (separate from the enzyme surface). The combination formed by an enzyme and its substrates is called the enzyme–substrate complex.
